## 1995 UNAVCO ANTENNA HEIGHT TESTS - PART I

## Experiment Purpose/Introduction

At the 1995 UNAVCO Users Meeting (May 2 and 3), Working Group 3 (WG3) asked the facility to conduct tests to determine the effect of different antenna mounts on GPS baseline results. Especially the effect of mounting antennas low above the ground versus high on a tripod was to be investigated.

## Map Of Antenna Test Range

The Table Mountain Observatory is a Department of Commerce facility. This observatory is approximately 10 km . north of Boulder, CO and is the location of the NOAA Precision Gravity Group (see Figure "Map From UNAVCO To Table Mountain Gravity Observatory" on page 1).This group has agreed to let UNAVCO conduct experiments near their buildings, and to use their electricity, phone, etc. The observatory is a large mesa (approximately 10 square km ) that allows for GPS antennas to be operated in a relatively benign multipath environment.

Figure 1 : Map From UNAVCO To Table Mountain Gravity Observatory

## Monument Description and Location

In early 1995, UNAVCO installed a geodetic quality pillar for future GPS experiments. This pillar will be used for the entire antenna experiment. In addition, the Equipment Services Group (ESG) has installed six 1.5 inch stainless steel rods adjacent to the NOAA pillar. These rods are mounted in approximately one meter of concrete and covered with 50 centimeters of dirt (figure 2). Each of these rods has a $5 / 8$ inch standard thread and dimple close to the ground. Finally, two stainless steel pins were installed into two existing concrete pads.

Figure 2 : Schematic of ESG Monument Diagram

Table 1 lists the names and types of each of the monuments. The relative location of the monu-
Table 1: Names and Types of Monuments

| Monument <br> Name | Monument Type | Marker Type |
| :---: | :---: | :---: |
| TBL0 | Concrete Pillar | $5 / 8^{\prime \prime}$ Thread with Dimple |
| TBL1 | Stainless Steel Pin | Dimple |
| TBL2 | Stainless Steel Pin | Dimple |
| DN01 | ESG Rod | $5 / 8^{\prime \prime}$ Thread with Dimple |
| DS01 | ESG Rod | $5 / 8^{\prime}$ Thread with Dimple |
| DE01 | ESG Rod | $5 / 8^{\prime \prime}$ Thread with Dimple |
| DW01 | ESG Rod | $5 / 8^{\prime}$ Thread with Dimple |

Table 1: Names and Types of Monuments

| Monument <br> Name | Monument Type | Marker Type |
| :---: | :---: | :---: |

| EE01 | ESG Rod | $5 / 8^{\prime \prime}$ Thread with Dimple |

ments is outlined in figure 3
Figure 3 : Schematic of the relative marker locations. "Diamond Sites" DW01, DN01 etc.
are spaced approximately 5 meters. TBL0 - TBL1 and TBL2 are spaced about 70 meters.

## Ground Truth

In addition to the GPS measurements, the location of the marks relative to the NOAA pillar (site TBL0) were determined using conventional surveying methods. The conventional survey was performed by UNAVCO engineer Jim Normandeau.

Survey \# 1. (conducted on 1 JUN 95) ${ }^{1}$
A traverse was completed using stations TBL0,TBL1, and TBL2. From stations TBL1 sideshots
were taken to the six UNAVCO antenna mounts. Due to high wind conditions sideshots were not taken from TBL2.

## Results of survey \#1. ${ }^{1}$

| STATION | Horizontal Distance $[\mathrm{m}]$ | Vertical Difference $[\mathrm{m}]$ |  |
| :--- | :---: | :---: | :--- |
|  |  |  |  |
| TBL1 to TBL0 | 57.884 | 0.986 | (TBL1 is lower than TBLO) |
| TBLO to TBL2 | 51.609 | -2.063 |  |
| TBL2 to TBL1 | 97.693 | 1.070 |  |
| TBL1 to DN01 | 50.782 | -0.562 |  |
| TBL1 to DW01 | 48.419 | -0.467 |  |
| TBL1 to DE01 | 55.045 | -0.617 |  |
| TBL1 to DS01 | 52.984 | -0.495 |  |
| TBL1 to WW01 | 58.853 | -0.233 |  |
| TBL1 to EE01 | 63.474 | -0.293 |  |

## Survey \# 2. (conducted on 15 JUN 95)

Due to significant differences (.004-.009m) between GPS measurements and theodolite/EDM measurements for four of the baselines the traverse and a sideshot to DN01 was redone. The results show the theodolite/EDM measurements are relatively consistent between surveys.

## Results of Survey \#2.

| STATION | Horizontal Distance [m] | Vertical Difference [m] |
| :--- | :---: | :---: |
| TBL1 to TBL0 | 57.886 | 0.988 |
| TBL0 to TBL2 | 51.609 | -2.063 |
| TBL2 to TBL1 | 97.692 | 1.067 |
| TBL1 to DN01 | 50.782 | -0.558 |

## Observation Schedule, Logs, And Data Availability

The following table summarizes the data that were collected during the first phase of the tests. All of these data are available from UNAVCO in RINEX or in raw format. Each file contains 23 hours of data. One hour per day was reserved for downloading and for changing the antenna setup. The columns in the table mean: DAY - day of the year, 1995, SITE - name of Table Mountain mark, RX\# - receiver number, RAWDATA - name of the raw-data file (RINEX files have the same prefix), SHGT - slant height from mark to bottom of preamp, VHGT - Vertical antenna height in meters to bottom of antenna preamp, ANTS - antenna serial number, UN\# - UNAVCO equipment tracking number, MONTYP - type of monument, SETUP - type of antenna mount, COMMENTS - describe what was done at the site.

| DAY | SITE | RX\# | RAWDATA |  | VISITID | SHGT | VHGT | ANTSN | UN\# | MONTYP | SETUPCOMMENTS |

These data, converted into RINEX, can be found in UNAVCO's anonymous ftp area.

## Mounting Types And Site Photos

Several types of antenna mounting were tested during the first phase of the experiment.
We used the conventional tripod (TP), setting up at about 1.5 meter, the UNAVCO-designed Levelling Spikemount (LM) as shown in figure 4, and a second $50-\mathrm{cm}$ UNAVCO Spikemount (S-50) as shown in figure 5. Photos show Trimble antennas mounted on the LM (figure 6) and the on the S-50 (figure 7).

Figure 4 : Schematic drawing and dimensions of the compact UNAVCO spike mount called the "leveling mount" (LM).

Figure 5 : Schematic drawing and dimensions of the $\mathbf{5 0 - \mathrm { cm }}$ UNAVCO spike mount called

## the S-50 in this report.

Figure 6 : Photo of the LM and a Trimble antenna at Table Mountain.

Figure 7 : Photo of the S-50 and a Trimble antenna at Table Mountain.

The LM requires a $5 / 8$ inch threaded bolt with a centered dimple for insertion of the pointed end of the spike. An antenna mounted with the LM is typically $10-20 \mathrm{~cm}$ above the ground or above a pillar, rooftop, etc. The S-50 can be mounted atop a benchmark and it requires a flat surface for bolting its feet to the ground. For the tests described here the $\mathrm{S}-50$ was mounted on concrete pads.

The advantage of spike mounts is that antennas are installed at known heights above benchmarks because the height is defined by the known length of the spike-mount.

## Data Analysis

The data from the tests were analyzed at the UNAVCO facility with the Bernese software. The Bernese software version 3.5 plus the Bernese Processing Engine (BPE) were used for the analysis.

The data were converted to RINEX using the TRRINEXO translator developed at the University of Bern. All data were processed as individual baselines (not in seven-station network solutions) and redundant baselines were formed. Processing for each of these baselines was done in the following sequence:
(1) Process L1 and resolve carrier phase ambiguities
(2) Process L2 "
(3) Process L3 (or LC) with resolved ambiguities
(4) Same as (1) but estimate tropospheric delay at one end of baseline every hour
(5) Same as (2) but estimate tropospheric delay at one end of baseline every hour
(6) Same as (3) but estimate tropospheric delay at one end of baseline every hour

Thus each baseline was analyzed in 6 different ways. Baseline results with tropospheric estimation were computed to determine if antenna phase center patterns are affected by the height, and/ or type of antenna mount. It has been shown that phase center pattern differences between antennas cause vertical baseline errors, especially when tropospheric parameters are estimated.

The reason for these vertical baseline errors is that phase center pattern differences between two antennas are interpreted as tropospheric delay differences between the two antennas by the GPS analysis software. Tropospheric delays are highly correlated to the station vertical, causing the observed vertical errors.

If the objective is highest geodetic precision it does not make sense to estimate tropospheric delays for baselines only several meters in length. In this case one would, for the short test baselines only compute an L1 solution. However, typical baseline analysis for geodetic GPS campaigns requires tropospheric estimation, using the ionospheric free linear combination L3. Thus if antenna mounting differences cause height errors for these solutions on short test baselines, these errors will also effect geodetic GPS campaigns.

## Results

The effect of the LM mount is most clearly demonstrated by summarizing the results of the DE01 - DN01 baseline. This baseline had three different setups. First, both antennas were mounted on tripods at $\sim 1.5$ meters. Second, both antennas were mounted on LM mounts near to the ground. Third, one end of the baseline was low on an LM and the other end of the baseline was high on a tripod.

Figure 8 : This figure shows the effect of different antenna set-up on the DE01 - to - DN01 baseline for the $\mathbf{L} 1$ solutions when no tropospheric parameters were estimated. The bottom panels show the antenna setup height on the DE01 marker (bottom left) and on DN01 (bottom right). Scatter in the length (top left) for the different setups is on the order of 0.5 mm , scatter in the height (top right) on the order of a few mm . This indicates that there is no significant effect on the $L 1$ results at the $1-\mathrm{mm}$ level and that the antenna setups were done cor-
rectly.

## DEDN.L1_NOTROP

Figure 9 : Same as Figure 8 for the $\mathbf{L} 3$ solutions when tropospheric delays were estimated hourly. Scatter in the length for the different setups is on the order of 1.5 mm , scatter in the height on the order of $\mathbf{4 c m}$. There is an apparent significant effect of the antenna setup
on the baseline results in the vertical.

## DEDN.L3_TROP

Baseline Length
Baseline Height

First Ant Height

Second Ant Height

DOY

In Figure 8 we show two things. (a) L1 solutions without estimating the troposphere are not affected by antenna setups and (b) There were no setup blunders above the 1-2 mm level during this experiment.

In Figure 9 we find that the setup significantly affects the baseline at the several-cm level. On days 157 and 158 and on days 164-166 both antennas are mounted on tripods. These results are in
good agreement. However, when DE01 is mounted low on the LM and DS01 is mounted high on a tripod on days $159-163$ results differ by almost -2 cm in the vertical from the tripod-tripod results. With the opposite setup on days $167-169$ results differ by almost +2 cm .

Similar results demonstrating that tripod-tripod results differ from mixed tripod-LM results at the $1-2 \mathrm{~cm}$ level were observed for many of the other baselines in the test diamond. Figure 11 plots all the mixed tripod-LM solutions about ground truth. This plot shows that there are differences of up to 16 millimeters between the GPS estimated and the ground truth solutions.

Figure 10 : Vertical component Scatter of Tripod-LM and LM-Tripod solutions within the "diamond" network. Ionosphere free L3 solutions with hourly troposphere parameter estimated.

A comparison of the tripod-tripod setups and the LM-LM setups with respect to ground truth is plotted in Figure 11. This figure shows that the scatter about ground truth of the low antenna setups is much larger than the scatter of the high antenna setups. The RMS of the LM-LM solutions about ground truth is 11 millimeters, while the tripod-tripod setups have an RMS of 1.4 millimeters.
Figure 11 : Vertical Scatter of LM-LM and Tripod-Tripod solutions within the "diamond"
network. Ionosphere free L3 solutions with hourly troposphere parameters estimated.

DESCRIBE S-50 RESULTS - to be completed

## Conclusions and Future Tests

Our tests have shown that geodetic results with the Trimble SST antenna are affected by antenna mounts and/or antenna mounting heights.
(a) Antenna mounting height and/or type of mount can affect geodetic baseline results at the several cm-level when tropospheric correction parameters are estimated.
(b) Even if both ends of a baseline are mounted on the same spike mount and approximately at the same height spike-mount to spike-mount baselines do not agree with tripod to tripod results if tropospheric parameters are estimated. This indicates that antenna phase patterns are very sensitive to the antenna environment for low setups. (See Figure 11)
(c) Tripod setups generally agree better with ground-truth than low spike-mount setups. (See Figure 11)

Results (a), (b) and (c) demonstrate that GPS investigators should avoid low near-the ground setups. We have not yet tested what happens with pillar, pole or rooftop mounts.

It is also not clear to what extend the observed effects are due to the ground and to what extend they are caused by the LM or S-50 mounts. Additional tests are required to investigate this.

We also plan to test if other antennas, such as the AOA choke ring antenna, are similarly sensitive to the setup if tropospheric parameters are estimated.
